

Scenario 11

An administrator is simulating a network in Mininet and wants to test a failover script. They need to manually bring down the link between two switches, s1 and s2, to see if traffic reroutes.

Question: What two commands would they use in the Mininet CLI to first bring the link down and then check the network's current link status?

Answer:

In the Mininet CLI, the administrator would use the following two commands:

- **1. Command to bring the link down:**

```
link s1 s2 down
```

(This command disables the link between switch s1 and switch s2.)

- **2. Command to check the network's current link status:**

```
links
```

(This command displays the current state of all links in the topology, showing whether each link is UP or DOWN.)
